Page 270, 5.1 Review Questions

1. Both Arrhenius and Bronsted Lowry acids contain $\mathrm{H}^{+}$ions. Definitions of a base differ. Arrhenius base contains $\mathrm{OH}^{-}$ions. Bronsted Lowry base accepts $\mathrm{H}^{+}$ion.
2. A Hydrogen atom contains 1 proton and 1 electron. When a $\mathrm{H}^{+}$ion is formed, the electron is given away, leaving a single proton.
3. 

One of the lone pairs of electrons on the oxygen atom of water will attract the $\mathrm{H}^{+}$ion from an acid.
4.

a) $\mathrm{NH}_{3}+\mathrm{H}_{3} \mathrm{PO}_{4} \leftarrow \mathrm{NH}_{4}^{+}+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$ base acid acid base

b) $\mathrm{H}_{2} \mathrm{PO}_{4}^{-}+\mathrm{SO}_{3}{ }^{2-} \leftarrow>\mathrm{HSO}_{3}{ }^{-}+\mathrm{HPO}_{4}{ }^{2-}$ acid base acid base

c) $\mathrm{CH}_{3} \mathrm{NH}_{2}+\mathrm{CH}_{3} \mathrm{COOH} \leftarrow \mathrm{CH}_{3} \mathrm{COO}^{-}+\mathrm{CH}_{3} \mathrm{NH}_{3}{ }^{+}$ base acid base acid
5.

6.

7.

b) HClO
8. a) Add a $\mathrm{H}^{+}$ion. Example: $\mathrm{CN}^{-}$becomes HCN
b) Remove a $\mathrm{H}^{+}$ion. Example: $\mathrm{HNO}_{2}$ becomes
$\mathrm{NO}_{2}^{-}$
9. a) $\mathrm{HO}_{2}^{-}$
b) $\mathrm{N}_{2} \mathrm{H}_{5}{ }^{+}$
c) $\mathrm{OC}_{6} \mathrm{H}_{5}^{-}$
d) $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{3}{ }^{+}$
10. A substance that is able act as both an acid or a base depending on the other substance present. Examples: $\mathrm{HSO}_{3}{ }^{-}, \mathrm{H}_{2} \mathrm{PO}_{4}{ }^{-}, \mathrm{HPO}_{4}{ }^{2-}, \mathrm{H}_{2} \mathrm{O}$ 11. a) As an acid: $\mathrm{HCO}_{3}^{-}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{CO}_{3}^{2-}+$ $\mathrm{H}_{3} \mathrm{O}^{+}$; As a base: $\mathrm{HCO}_{3}^{-}+\mathrm{H}_{2} \mathrm{O} \leftarrow>\mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{OH}^{-}$ Use litmus paper to test the solution. If it is acidic, the litmus will turn red. If it is basic, the litmus will turn blue.
b) As a base. $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CO}_{2}$ can be written as $\mathrm{H}_{2} \mathrm{CO}_{3}$.
12.

Page 275, Quick Check

1. Concentrated acids have a high molarity (ex. 6 M acid) whereas a strong acid is one that ionizes completely (ex. HCl ). You can have a concentrated weak acid - such as 6 M HF .
2. $\mathrm{HNO}_{3}$ is a strong acid so ionizes completely:
$\mathrm{HNO}_{3}(a q)+\mathrm{H}_{2} \mathrm{O}(l) \rightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{NO}_{3}^{-}(a q)$ 1.0 M $\quad 1.0 \mathrm{M}$
$\begin{aligned} & \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(l) \\ & (\mathrm{aq}) \\ & 1.0 \mathrm{M}\end{aligned} \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{COO}^{-}$
very few very few

Because both acids are the same concentration, but $\mathrm{HNO}_{3}$ is strong and $\mathrm{CH}_{3} \mathrm{COOH}$ is weak, the $\mathrm{HNO}_{3}$ will have more ions in solution.
3. In 0.1 M NaOH : a bright light In $0.1 \mathrm{M} \mathrm{NH}_{3}$ : very dim light or no light visible $\mathrm{NaOH}(a q) \rightarrow \mathrm{Na}^{+}(a q)+\mathrm{OH}^{-}(a q) \quad \mathrm{NH}_{3}(a q)+$ $\mathrm{H}_{2} \mathrm{O}(l) \leftarrow \mathrm{NH}_{4}^{+}(a q)+\mathrm{OH}^{-}(a q)$
4. No, $\mathrm{Cl}^{-}$will not accept an $\mathrm{H}^{+}$ion. HCl is a strong acid and completely ionizes.

1. $\mathrm{HF}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(l)<\rightarrow \mathrm{H}_{3} \mathrm{O}^{+}(a q)+\mathrm{F}^{-}(a q) K_{a}=$ $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]\left[\mathrm{F}^{-}\right] /[\mathrm{HF}]$
2. NaOH is a strong base, which means that it ionizes completely. There is no equilibrium present, so no $K_{b}$.
3. $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NH}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(I) \quad<\rightarrow \mathrm{OH}^{-}(a q)+$ $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NH}_{3}{ }^{+}(\mathrm{aq})$ $\mathrm{K}_{b}=\left[\mathrm{OH}^{-}\right]\left[\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NH}_{3}{ }^{+}\right] /\left[\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{NH}_{2}\right]$
4. Acid: $\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(l)<\rightarrow \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+$ $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})$

3. Methanoic acid $>$ carbonic acid $>$ boric acid $>$ phenol
$\mathrm{HCOOH}>\mathrm{H}_{2} \mathrm{CO}_{3}>\mathrm{H}_{3} \mathrm{BO}_{3}>\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}$

## Page 281, Quick Check

1. There are more oxygen atoms (which are highly electronegative) attached to the central nitrogen atom - therefore, the $\mathrm{O}-\mathrm{H}$ bond in Acid 1 is more polarized than in Acid 2 (as 3 oxygen atoms pull electrons away from hydrogen to a greater extent than 2 oxygen atoms do) and hydrogen will be donated more easily in Acid 1. As a result, Acid 1 is stronger than Acid 2.
2. Since the presence of more hydrogen atoms bound to the central atom strengthens the bond between hydrogen and that atom, HBr , $\mathrm{HCl}, \mathrm{HI}>\mathrm{H}_{2} \mathrm{Se}, \mathrm{H}_{2} \mathrm{~S}, \mathrm{H}_{2} \mathrm{O}>\mathrm{CH}_{4}$ in terms of acid strength.
$\mathrm{l}>\mathrm{Br}>\mathrm{Cl}$ in terms of size. And as the halogen atoms' size increases, the bond length between the halogen atom and hydrogen increases, so the bond strength decreases, allowing H to be donated more easily and making the acid stronger. Therefore, $\mathrm{HI}>\mathrm{HBr}>\mathrm{HCl}$ in terms of acid strength.
For the same reason, $\mathrm{Se}>\mathrm{S}>\mathrm{O}$ in terms of size and $\mathrm{H}_{2} \mathrm{Se}>\mathrm{H}_{2} \mathrm{~S}>\mathrm{H}_{2} \mathrm{O}$ in terms of acidity. Therefore, $\mathrm{HI}>\mathrm{HBr}>\mathrm{HCl}>\mathrm{H}_{2} \mathrm{Se}>\mathrm{H}_{2} \mathrm{~S}>\mathrm{H}_{2} \mathrm{O}$ $>\mathrm{CH}_{4}$ in terms of acid strength.
3. The more oxygen atoms are attached to the central atom, the more polarized the $\mathrm{O}-\mathrm{H}$ bond is. Therefore, $\mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{HClO}_{4}>\mathrm{HClO}_{3}$, $\mathrm{HBrO}_{3}, \mathrm{H}_{2} \mathrm{SO}_{3}$ in terms of acid strength.

Between $\mathrm{H}_{2} \mathrm{SO}_{4}$ and $\mathrm{HClO}_{4}$, since Cl is more electronegative than $\mathrm{H}_{2} \mathrm{SO}_{4}$ and pulls electrons away from H more than S does, hydrogen in $\mathrm{HClO}_{4}$ is donated more easily than in $\mathrm{H}_{2} \mathrm{SO}_{4}$. Therefore, $\mathrm{HClO}_{4}>\mathrm{H}_{2} \mathrm{SO}_{4}$ in terms of acid strength.
For similar reasons, $\mathrm{H}_{2} \mathrm{SO}_{3}$ is weaker than $\mathrm{HClO}_{3}$ and $\mathrm{HBrO}_{3}$ (since Cl and Br are both electronegative halogens while $S$ is not). Finally, since Br is less electronegative than Cl , the $\mathrm{O}-\mathrm{H}$ bond is more polarized in chloric acid than in bromic. This allows hydrogen to be donated more easily. Therefore, $\mathrm{HBrO}_{3}>$ $\mathrm{HClO}_{3}>\mathrm{H}_{2} \mathrm{SO}_{3}$.
Therefore overall, $\mathrm{HClO}_{4}>\mathrm{H}_{2} \mathrm{SO}_{4}>\mathrm{HBrO}_{3}>$ $\mathrm{HClO}_{3}>\mathrm{H}_{2} \mathrm{SO}_{3}$.
4. Methanoic acid and benzoic acid have main carbon chain lengths of 1 while ethanoic acid has a carbon chain of length 2.
Therefore, ethanoic acid's $\mathrm{O}-\mathrm{H}$ bond is the least polarizable. Furthermore, benzoic acid has a huge group of carbon atoms - a benzene ring (phenyl group) - attached to the 1 carbon chain that allows any charge to disperse between the many carbon \& hydrogen atoms in the benzene group, so its $\mathrm{O}-\mathrm{H}$ bond is the less polarizable than that of methanoic acid.
Therefore, methanoic acid $>$ benzoic acid $>$ ethanoic acid in terms of polarity of O-H bond and consequently strength.

2. The $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$increased because the pH decreased. A 5 unit pH decrease corresponds to a
$10^{5}$ times increase in hydronium concentration.
3. Initial pH (prior to dilution) $=1.00$

After the dilution, the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=2.00$

Just after the equivalence point was reached: $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=2.2 \times 10^{-10} \mathrm{M}$
3. Because pH is defined as a negative logarithm, converting a negative pH value to a concentration involves the following:
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=16 \mathrm{M}$
The pH scale is not necessary to conveniently express concentrations this large.

2. 

a) As a solution becomes more acidic, both $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$and pOH increase and both $\left[\mathrm{OH}^{-}\right]$and pH decrease.
b) A basic solution has a pOH value which is less than 7 , and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$which is greater than $10^{-7} \mathrm{M}$.
c) If the pH of a solution equals 14.0 , the $\left[\mathrm{OH}^{-}\right]$equals 1 M . (1 sig. digit)
d) If the pOH of a solution decreases by 5 , then the $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$has decreased by a factor of $10^{5}$.
3. We would expect the $\mathrm{K}_{w}$ for water at $10^{\circ} \mathrm{C}$ to be less than $10^{-14}$ because the autoionization of water is endothermic. Regardless of the temperature, pure water is always neutral and so:
For pure water at any temperature: $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{OH}^{-}\right] \quad$ and $\mathrm{pH}=\mathrm{pOH}$
Therefore, because $\mathrm{pH}+\mathrm{pOH}=\mathrm{pK}_{\mathrm{w}}$, when we calculate the value of $\mathrm{pK}_{\mathrm{w}}$, the pH (and also the pOH ) must be half the value of $p K_{w}$.
$\mathrm{pK}_{w}=-\log \left(2.55 \times 10^{-15}\right)=14.593$ Therefore, $\mathrm{pH}($ and pOH$)=14.5934=7.297$

1. The pH of a solution is defined as the negative logarithm of the concentration of hydronium ions. Equation: $\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$
The pOH of a solution is defined as the negative logarithm of the concentration of hydroxide ions. Equation: $\mathrm{pOH}=-\log \left[\mathrm{OH}^{-}\right]$
2. Sorenson's logarithmic pH and pOH scales are a convenient and compact way of expressing the typically very small concentrations of hydronium and hydroxide ions respectively and the extent by which they can change in aqueous solutions

An alternative approach would be to calculate the total number of moles of hydronium ions from the acid solutions and then subtract that total from the moles of hydroxide ions from the basic solution. The excess moles of hydroxide ions present in the final 100.0 mL are then used to calculate final pH .

## Page 314, Quick Check

1. The amount of water that a weak acid will convert to hydronium ions is insignificant compared to the magnitude of water's concentration ( 55.6 M ). The concentration of water is thus assumed to be constant and so is not included in an ICE table.
2. Because the $K_{a}$ of a weak acid is normally so much greater than $K_{w}$, we can assume that the initial $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$resulting from the autoionization of water is insignificant compared to the equilibrium $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ resulting from the ionization of this weak acid.
3. The value of $K_{a}$ is small enough compared to the initial concentration of the acid that the percent of the acid which actually ionizes will not significantly change that original concentration. Remember that this assumption is only valid if the percent ionization of the weak acid is $\leq 5 \%$.
